Abstract

Since 1985 increasingly more foxes have been recorded from cities in Switzerland. The inquiry of town officials showed that foxes are observed in 28 out of the 30 largest Swiss cities today and breeding dens are known in 20 of these cities. Urban foxes are observed more often than one would expect in larger cities than in smaller towns. In Zürich, the largest city in Switzerland, urban foxes were very scarce until the early 1980s. According to the hunting statistics, from 1985 onwards, there was a drastic increase in the urban fox population. In the adjacent rural areas, there was also a clear but less extreme increase in the fox population from 1984 onwards due to successful vaccination campaigns against rabies. As an explanation for the presence of foxes in urban settlements we suggest two alternative hypotheses, which focus either on the population pressure in the rural areas or on the behavioural adaptations of urban foxes. The presence of foxes in urban areas influences behaviour and attitudes of people towards urban wildlife and it has consequences for the management of foxes and the treatment of zoonoses such as rabies and the alveolar echinococcosis.

Key words: Vulpes vulpes, urban habitat, invasion, adaptation

Introduction

Since 1985 fox populations have experienced a drastic increase in Switzerland (Breitenmoser et al. 2000). Apart from this development in rural areas, increasingly more foxes have been recorded from large Swiss conurbations and cities such as Zürich and Geneva. Game wardens and wildlife biologists have observed foxes in urban areas; people having noticed foxes in their gardens turned to local officials for information; pictures and articles about foxes in the middle of residential areas have been published. Are these records just occasional observations or do they indicate the colonisation of a new habitat by the red fox? Red foxes living in urban areas are known from Great Britain where urban foxes have been observed in cities such as London since the 1930s (Tiggle 1967; Beames 1969, 1972; Page 1981). In the 1970s and 1980s, fox populations in British cities reached densities of up to five fox family groups per km² (representing 12 adults on average), densities which had never been

1615-5047/01/66/03-155 $ 15.00/0.
observed so far (Harris 1981; Harris and Rayner 1986a). Similar fox population densities were nowhere recorded in urban areas outside of Great Britain, either on the European continent or in other parts of the distribution areas of the red fox. Therefore, urban foxes were thought to be a British phenomenon (Harris 1977; Macdonald and Newdick 1982). In the 1970s and 1980s, the fox population on the European continent experienced a heavy rabies epizootic, which reached Switzerland and other densely populated cantons of Switzerland (area 1661 km², 683 inhabitants per km²). Rayner 1986a). Similar fox population densities on the European continent experienced a heavy rabies epizootic, which reached Switzerland in 1967 (Steck et al. 1980; Ser et al. 2000). After the success of oral vaccination campaigns against rabies, started in Switzerland in 1978 (Wande cooler et al. 1988), the fox population recovered again from 1985 onwards (Kappler 1991; Breitenmoser et al. 2000). At that same time, foxes were increasingly observed in human settlements. Our objectives in this study are to investigate the present situation in large Swiss settlements, to evaluate the recent development of the fox population in Zurich, the largest conurbation of Switzerland, and to compare it with the trend in surrounding rural areas.

Material and methods

Study area
Switzerland is a diverse and mountainous country. 24% of its total area of 40,000 km² (excluding lakes), are above 2000 meters in elevation where fox population density is low. The remaining 76% of the country forms heterogeneous and mostly good, the fox population (FEDERAL OF STATISTICS 1998). Forest and agricultural areas around the urban area are referred to as the rural area of the city in the following. As far as hunting is concerned, the city of Zurich is organised as a game sanctuary. The city of Zurich belongs to the canton of Zurich, one of the most densely populated cantons of Switzerland (area 1661 km², 683 inhabitants per km²).

The present distribution of urban foxes in Switzerland

During a television series about urban foxes in spring 1997, the public was called to report fox sightings in Swiss cities. The sightings were recorded personally by collaborators of the Integrated Fox Project. Only fox sightings within human settlements were recorded. As the call on TV was biased towards the German speaking part of Switzerland, the scanty information from the French and Italian speaking regions of the country were excluded from further analyses. The program actus Estabrook and Estabrook 1989) was used for the statistical test, which performs randomised contingency tables and gives probabilities for deviations from expected values. In spring 1999 we carried out a phone inquiry with people or institutions in charge of wildlife management in all 30 Swiss cities (communities) with more than 20000 inhabitants (FEDERAL OF STATISTICS 1998). The experts were asked about occurrence and abundance of urban foxes, evidence of breeding dens in the urban area, the year of the first urban fox sightings and the current trend in the urban fox population. In cities with official game wardens (18 out of 30), they were interviewed, in all other cities we questioned non-professional hunters and the nature conservation officials. In the conurbation of Geneva (three communities with >20000 inhabitants) our contacts were wildlife biologists running an urban fox project; in Zurich we knew the situation from our own project.

Development of the urban fox population in the city and the canton of Zurich

There are no direct figures on the red fox population available. Therefore its development has to be shown indirectly through hunting records and other recorded causes of death. Longtime figures for an urban area are available for the city of Zurich, because it has been a game sanctuary since 1929. All wildlife management tasks in the city and the canton of Zurich are exclusively performed by official game wardens, therefore the hunting result is recorded and the locations of dead foxes (shot or found dead) are known. For comparison of the data from the canton and the city of Zurich, we used the HIPD (hunting indicator of population density; Bögel et al. 1974). We defined the HIPD as the annual number of foxes hunted per km² excluding lakes and areas above 2000 meters. We did not include data on foxes with other causes of death than hunting because generally these data have only been available since 1965.

To compare data from urban and adjacent rural areas within the city of Zurich, we used a total number of foxes shot or found dead (available from 1960 to 1997), and additionally numbers of the two mortality factors "shot" and "found dead" (mostly road casualties; for the whole city available since 1996, for urban and adjacent rural areas separately available since 1984). To analyse the development of the fox population in the city of Zurich we performed simple linear regressions because the fit of regression of the two mortality factors on the years 1984 to 1997 did not improve by exponential or logistic functions.

Results

The present occurrence of urban foxes in Switzerland

After the call for urban fox sightings on Swiss Television in spring 1997, 194 sightings from 78 different towns and villages of the German-speaking part of Switzerland were reported. 138 sightings came from towns with more than 10000 inhabitants (Tab. 1). Of those, more sightings than expected concerned cities with more than 50000 inhabitants (randomisation test, p < 0.01), and less sightings than expected from towns with 10000 – 20000 inhabitants (p < 0.05; Tab. 1).

According to our inquiry among institutions in charge of wildlife management in 8 out of 9 cities with >50000 inhabitants, and in 18 of the 19 cities with 20000 – 50000 inhabitants, foxes were occasionally found or common (Fig. 1, Tab. 2). Foxes seem not to have decreased since 1985 – 1999 (Table 2).

be present in two towns only: in Bern, situated on the Swiss Plateau, and in Lugano, a city in the southern Alps.

In all 13 towns where foxes were reported to be common, they were observed throughout the urban area, (including the centre), and they were breeding in the urban area also (Tab. 2). In 4 cities with more than 50,000 inhabitants (Zurich, St. Gallen, Luzern, Biel), breeding dens are known even in the very city centre. In most cities (17 out of 28), urban foxes have been perceived as a recent phenomenon since 1985.

No geographical trend can be recognised as far as the beginning of settlement in different cities is concerned.

Only in the conurbation of Geneva, with three cities (communities) with > 20,000 inhabitants (Geneva, Lancy, Vernier, Tab. 2) the population is said to decrease because of an outbreak of sarcoptic mange in 1996 (C. Fischer, pers. comm.).

Development of the urban fox population in the city of Zurich

The HIPD of the canton of Zurich and the city of Zurich correlate significantly (Spearman, \( r = 0.66, p < 0.001 \); Fig. 2a), the HIPD in the canton always being higher than in the city. Additionally, the HIPD of canton and city are strongly influenced by rabies trends between 1967, the year when rabies reached Switzerland, and 1985, the year with the last cases of rabies found on foxes in the canton of Zurich (Fig. 2a, b).

According to the HIPD, the fox population in the city of Zurich and in the whole area of the canton of Zurich seems to have developed in parallel at least since the beginning of the 1970s. Both HIPDs are higher after the rabies episode than before. The average of the HIPD from 1993 to 1997 compared to the average of the HIPD from 1960 to 1964 is by 1.7 times higher (2.02 vs. 1.19) in the canton and 3.7 times higher (126 vs. 0.09) in the city of Zurich, indicating a stronger population increase in the canton than in the city, both in the urban and in the adjacent rural part of the city. From 1985 to 1997 the number of foxes shot or found dead in the whole city increased by 20 times from 11 to 223. This trend is true for both mortality factors “shot” and “found dead” and examined separately for urban and adjacent rural areas (Tab. 3). Yet the increase in the number of foxes found dead was stronger in the urban than in the rural area (difference of coefficients, \( t_{24} = 4.11, p < 0.001 \)).

Discussion

Today, urban foxes are recorded in almost all cities of Switzerland. The presence of breeding dens in urban areas up to the city centres indicates that foxes really live in the cities and are not just occasional roamers from the vicinity. We ascribe differences...
Fig. 3. Fox mortality (animals shot or found dead) in urban and rural areas in the city of Zurich from 1960 to 1997. The years 1973-1976 and 1982-1983 there are only total numbers of dead city foxes available (white bars). The years with rabies cases within 5 km of the city centre (Kappeler 1991) are marked with black bars.

Table 3. The increase of numbers of recorded dead foxes within the city borders of Zurich, described by the linear regression of the two mortality factors “shot” and “found dead” (mostly road casualties) from 1984 to 1997.

in fox population densities in Swiss cities of today mainly to the fact that urban foxes have been a recent phenomenon and the development is still going on. Our call for fox sightings on Swiss television revealed that more foxes are recorded from larger towns than from smaller ones, a relation that was also observed by Macdonald and Newdick (1982) in Great Britain. This could be because larger towns may have a higher proportion of suburban habitat, where the highest fox densities are found (Harris and Rayner 1986 b).

Although red foxes generally avoid the direct presence of humans, some foxes have lived in the neighbourhood of humans settlements for a long time, shown, e.g., by the naturalist Schinz (in Ineichen 1997), who noted in 1842, that red foxes had always lived in the moats surrounding the city of Zurich. The hunting statistics of the city of Zurich show that foxes have been present in the urban area since the early 1960s, but such observations remained isolated cases. In 1985 the situation began to change. Due to successful oral vaccination campaigns against rabies, the fox population in Switzerland started to recover (Breitenmoser et al. 2000), which is recorded in other European countries, as well (e.g. Vos 1993, Artois et al. 1997). It was parallel to this general trend, when the urban fox population in the city of Zurich and in most other Swiss cities showed a drastic increase. However, hunting statistics have to be interpreted cautiously, because they do not only correlate with the real fox populations but are also influenced by other factors such as the preferences of the hunters (Macdonald and Vogt 1985; Goszczynski 1989) or outbreaks of zoonoses (Kappeler and Wandel 2000). A high hunting pressure most probably lasted during the whole period of rabies from 1967 until at least to the end of the 1980s. Therefore, the low HIPD during this period presumably reflects low densities of fox populations. With the decrease of rabies the motivation to hunt foxes probably decreased drastically. The HIPD, on the one hand, was still increasing during the 1990s. We therefore suggest that the real trend of fox populations is underestimated by hunting statistics.

The fox population in the canton of Zurich with its high degree of urbanisation must be even more underestimated by the HIPD, because foxes are hardly ever shot in most urban areas, where hunting generally is not permitted.

The game sanctuary of the city of Zurich is an exception where a constant hunting regime is maintained by official game wardens. The significant correlation of the development of foxes “shot” and “found dead” within the city confirms, that the increasing numbers of dead foxes are not only the result of an increased shooting effort.

A similar development of urban foxes as in Switzerland recently took place in other parts of the distribution area of the red fox which is shown by reports, e.g., from Oslo, Norway (Christensen 1985), Arhus, Denmark (Moller Nielsen 1990), Stuttgart, Germany (T. Romo, pers. comm.), Toronto, Canada (Vogt 1988) and Sapporo, Japan (K. Uraguchi, pers. comm.). The questions arises why the invasion of urban habitat started and which factors caused this new development.

According to Harris and Rayner (1986c), the colonisation of British towns already started in the 1930s. During these years there was a boom of private house construction resulting in large districts of middle-class suburbs with low-density housing, and medium-sized gardens. This is the type of habitat which Harris and Rayner (1986 b) found to be favoured by foxes. Once established in these residential suburbs, foxes moved further into the city and also colonised less favoured habitats. Harris and Rayner (1986b) found urban foxes to be less common in areas consisting of council-rented housing, in city centres, and around industrial areas.

The colonisation of Swiss cities by foxes resulted in a similar phenomenon as known from Great Britain. However, the underlying cause for the rise of the urban fox populations seems to be different, because the development of Swiss cities in the past thirty years was unlike British cities in the 1930s. We propose two hypothetical explanations for the presence of urban foxes: The population pressure hypothesis (PPH) and, as an alternative, the urban island hypothesis (UIH).

The population pressure hypothesis PPH postulates that urban foxes are simply intruders from the adjacent rural areas. These foxes invade in human settlements because of a high population density in rural areas. According to the PPH, urban areas would provide suboptimal habitats for foxes, the dynamics of an urban fox population would closely correlate with the trend of the fox population in the adjacent rural areas, and the urban fox population would genetically not be different from the adjacent rural population (Rousset 1999).

The alternative urban island hypothesis UIH postulates that urban foxes have adapted to specific urban conditions such as high density of human population. Therefore, urban foxes would be able to use specific urban resources such as scavenged food items or special hiding places during daytime. The dynamics of such an
urban fox population would be independent from the trend in the adjacent rural areas. The colonisation of urban areas could have been initiated by the behavioural adaptations of a few foxes that gave them access to exploit human settlements as a free niche. As only a few individuals founded the new urban population, we would expect it to be genetically isolated from the population in the rural surroundings.

The simultaneous emerging of urban foxes throughout Switzerland along with the increasing fox population indicates that the high population pressure has at least initiated the colonisation of the founder individuals into the cities. MACDONALD and NEWDICK (1982) suggested that there was no strict division between rural and urban foxes in Oxford, because they had radio-tracked foxes which regularly commuted between urban and rural areas. Nevertheless, living in the city requires special adaptations, and many anecdotal observations reveal that foxes indeed have adapted to this exceptional environment. Further research on resource exploitation and genetic structure of the urban fox population will allow to compare the two hypotheses. Furthermore, the zoological alveolar echinococcus (AE), caused by the small fox tapeworm Echinococcus multilocularis, could become more important through the increase of urban fox populations. In Switzerland, the incidence rate of human AE has not significantly changed over the past 36 years, suggesting a stable epidemiological situation (ECKERT and DEPLAZES 1999), but regarding the long incubation period of AE of 5–15 years, it would be advisable to study this zoonosis further, especially in urban areas. Results of such studies could have an important impact on the management of urban fox populations.

Acknowledgements

The authors thank all collaborators involved in the Integrated Fox Project. We especially thank CLAUS FISCHER, who conducted the inquiry of Fuchs in the French part of Switzerland and provided useful information on the urban fox population of Geneva, and CHRISTIAN STAUFFER for his generous collaboration and for providing access to the data of the game sanctuary of Zurich. We thank ALEXANDER MATTHIS, CLAUS FISCHER, CHRISTIAN STAUFFER, and JEAN-MARC WEBER for comments on an earlier draft. We also thank the game wardens and people in charge of wildlife management in the 30 large cities of Switzerland. The study was supported by the Swiss National Science Foundation (grant no. 31-47031.96), the Fonds zur Förderung des akademischen Nachwuchses FAN of the Zürcher Hochschul-Verein and the Swiss Federal Office for Education and Science (EU FAIR Projekt CT97-3515/BWB Nr. 97.0586).

Zusammenfassung

Die Entstehung urbaner Fuchspopulationen in der Schweiz

Feeding selectivity and food preference of Ctenomys talarum (tuco-tuco)

By JUANA C. DEL VALLE, MARIA I. LOHFELT, VIVIANA M. COMPARATORE, MARIA S. CID, and CRISTINA BUSCH

Departamento de Biología, Universidad Nacional de Mar del Plata, Mar del Plata Argentina

Abstract

We tested feeding selectivity and food preference of Ctenomys talarum (tuco-tuco). To test feeding selectivity, above ground and below ground plant biomass from the field was determined and botanical composition of the diet was estimated in stomach contents using microhistological techniques. Feeding preferences were studied carrying out laboratory cafeteria experiments. Ctenomys talarum behave as generalist and opportunistic herbivores consuming the greater part of species present in the grassland. The above ground portion was preferred over the subterranean one. Grasses constituted 94% of the above ground vegetative fraction consumed and were generally selected in preference trials also showed that C. talarum prefer above ground parts of grasses to other choices.

Key words: Ctenomys talarum, diet, feeding selectivity, food preference

Introduction

Rodents of the genus Ctenomys (tuco-tucos) are subterranean herbivores whose populations are distributed in a discontinuous pattern throughout Argentina, Paraguay, Bolivia, Uruguay, Peru, and Chile, and northern Brazil (Woods 1984). Most herbivores inhabit a biotope in which the food resources are important to both burrow location and burrow density of the fox (Vulpes vulpes) in an area of London. J. Zool. (London) 194, 485-491.
